(Received March 30, 2014, Revised October 9, 2014, Accepted October 28, 2014)

#### Abstract

The free vibration of rotating Euler-Bernoulli beams with the thickness and/or width of the cross-section vary linearly along the length is investigated by using the Adomian modified decomposition method (AMDM). Based on the AMDM, the governing differential equation for the rotating tapered beam becomes a recursive algebraic equation. By using the boundary condition equations, the dimensionless natural frequencies and the closed form series solution of the corresponding mode shapes can be easily obtained simultaneously. The computed results for different taper ratios as well as different offset length and rotational speeds are presented in several tables and figures. The accuracy is assured from the convergence and comparison with the previous published results. It is shown that the AMDM provides an accurate and straightforward method of free vibration analysis of rotating tapered beams.

Keywords: adomian modified decomposition method; rotating tapered beam; taper ratio; natural frequency; mode shape

## 1. Introduction

The determination of natural frequencies and mode shapes of rotating tapered beams is very important for the design of helicopter blades, airplane propellers and wind turbines etc. As a result, the free vibration analysis of rotating tapered beams has been extensively studied by many researchers with great success. For examples, the publications (Banerjee 2000, Banerjee et al. 2006, Banerjeea and Jackson 2013) used the dynamic stiffness method based on Frobenius solutions to solve the free bending vibration of the uniform and tapered rotating beam. The publications (Wang and Wereley 2004, Vinod et al. 2007) imposed spectral finite element method for vibration analysis of rotating blades with uniform tapers under cantilever and hinged boundary conditions. The publications (Ozdemir and Kaya 2006a, b, Rajasekaran 2013) applied differential transformation method (DTM) for the free vibration analysis of tapered rotating beams. Bazoune (2007) discussed the effect of taper ratio on the natural frequencies of the beam using finite element method.

Recently, a relatively new computed approach called Adomian modified decomposition method (AMDM) (Adomian 1994) has been applied to the free vibration problem for several beam structures, such as linear and nonlinear tapered beam under general boundary conditions (Hsu et

[^0]al. 2008, Mao and Pietrzko 2012), multiple-stepped beams (Mao 2011), elastically connected multiple-beam systems (Mao 2012) and uniform rotating beam (Mao 2013). The AMDM has shown reliable results in providing analytical approximation that converges rapidly (Adomian 1994). In this study, the AMDM is extended to analyze the free vibration for the rotating tapered Euler-Bernoulli beams under various taper ratios, rotating speeds and offset lengths. The AMDM is a straightforward and powerful method for solving linear and nonlinear differential equations. The main advantages of AMDM are computational simplicity and do not involve any linearization, discretization, perturbation. In AMDM the solution is considered as a sum of an infinite series, and rapid convergence to an accurate solution.

Using the AMDM, the governing differential equation for the rotating tapered beam becomes a recursive algebraic equation. The boundary conditions become simple algebraic frequency equations which are suitable for symbolic computation. Moreover, after some simple algebraic operations on these frequency equations, the natural frequency and corresponding closed-form series solution of mode shape can be determined simultaneously. Finally, the effects of the taper ratios, rotating speeds and offset lengths on the natural frequencies and mode shapes are investigated. The results are compared with previous published ones to demonstrate the accuracy and efficiency of the proposed method.

## 2. AMDM for the rotating beams

Consider the free vibration of a rotating tapered cantilever Euler-Bernoulli beam with length $L$, both continuously linearly varying width $b(x)$ and thickness $h(x)$, as shown in Fig. 1. The variation of the width and thickness along beam length $L$ are defined as

$$
\begin{equation*}
b(x)=b_{0}\left(1-c_{b} \frac{x}{L}\right), \quad h(x)=h_{0}\left(1-c_{h} \frac{x}{L}\right) \tag{1}
\end{equation*}
$$

where $b_{0}$ and $h_{0}$ are the width and thickness at the root of the beam, respectively. $c_{b}$ and $c_{h}$ are the width and thickness taper ratios, respectively.

Fig. 1 A rotating tapered cantilever Euler-Bernoulli beam

The partial differential equation describing the out-of-plane bending vibration of a rotating tapered beam is as follows (Banerjee et al. 2006, Wang and Wereley 2004)

$$
\begin{equation*}
\frac{\partial^{2}}{\partial x^{2}}\left[E I(x) \frac{\partial^{2} w(x, t)}{\partial x^{2}}\right]+\rho A(x) \frac{\partial^{2} w(x, t)}{\partial t^{2}}-\frac{\partial}{\partial x}\left[T(x) \frac{\partial w(x, t)}{\partial x}\right]=0 \tag{2}
\end{equation*}
$$

where $E$ and $\rho$ are Young's modulus and the density of the beam, respectively. $A(x)$ and and $I(x)$ are the cross-sectional area and the cross-sectional moment of inertia of the beam, respectively.

$$
\begin{gather*}
A(x)=b(x) h(x)=A_{0}\left(1-c_{b} \frac{x}{L}-c_{h} \frac{x}{L}+c_{b} c_{h} \frac{x^{2}}{L^{2}}\right)  \tag{3}\\
I(x)=\frac{b(x) h^{3}(x)}{12}=I_{0}\left(1-c_{b} \frac{x}{L}\right)\left(1-c_{h} \frac{x}{L}\right)^{3}=I_{0}\left(1+\alpha_{1} \frac{x}{L}+\alpha_{2} \frac{x^{2}}{L^{2}}+\alpha_{3} \frac{x^{3}}{L^{3}}+\alpha_{4} \frac{x^{4}}{L^{4}}\right) \tag{4}
\end{gather*}
$$

where $A_{0}=b_{0} h_{0}, I_{0}=\frac{b_{0} h_{0}^{3}}{12}, \alpha_{1}=-\left(c_{b}+3 c_{h}\right), \alpha_{2}=3 c_{h}\left(c_{b}+c_{h}\right), \alpha_{3}=-c_{h}^{2}\left(3 c_{b}+c_{h}\right), \alpha_{4}=c_{b} c_{h}^{3}$.
$T(x)$ in Eq. (2) is the axial force due to the centrifugal stiffening and is given by the following (Banerjee et al. 2006, Wang and Wereley 2004)

$$
\begin{equation*}
T(x)=\int_{x}^{L}\left[\rho A(x) \Omega^{2}(r+x)\right] d x \tag{5}
\end{equation*}
$$

where $\Omega$ is the angular rotating speed of the beam, $r$ is offset length between beam and rotating hub.

According to modal analysis approach (For harmonic free vibration), the $w(x, t)$ can be separated in space and time

$$
\begin{equation*}
w(x, t)=\phi(x) e^{i o t} \tag{6}
\end{equation*}
$$

where $i=\sqrt{-1}, \phi(x)$ and $\omega$ are the structural mode shape and the natural frequency, respectively.
Substituting Eq. (6) into Eq. (2), then separating variable for time $t$ and space $x$, the ordinary differential equation for the rotating beam can be obtained

$$
\begin{align*}
& E I(x) \frac{d^{4} \phi(x)}{d x^{4}}+2 E \frac{d I(x)}{d x} \frac{d^{3} \phi(x)}{d x^{3}}+E \frac{d^{2} I(x)}{d x^{2}} \frac{d^{2} \phi(x)}{d x^{2}} \\
& -T(x) \frac{d^{2} \phi(x)}{d x^{2}}-\frac{d T(x)}{d x} \frac{d \phi(x)}{d x}-\rho A(x) \omega^{2} \phi(x)=0 \tag{7}
\end{align*}
$$

To rewrite Eqs. (5) and (7) into dimensionless form, we define

$$
\begin{equation*}
X=\frac{x}{L}, R=\frac{r}{L}, U=\sqrt{\frac{\rho A_{0} \Omega^{2} L^{4}}{E I_{0}}}, \Phi(X)=\frac{\phi(x)}{L}, \lambda=\sqrt{\frac{\rho A_{0} \omega^{2} L^{4}}{E I_{0}}} \tag{8}
\end{equation*}
$$

where $\lambda$ is the dimensionless natural frequency, and the $n$th dimensionless natural frequency is denoted as $\lambda(n) . U$ is the dimensionless rotating speed of the beam.

Substituting Eq. (4) into Eq. (5), the axial force $T(x)$ within a rotating beam can be expressed as

$$
\begin{equation*}
T(x)=\frac{E I_{0}}{L^{4}} U^{2}\left(\beta_{0}+\beta_{1} \frac{x}{L}+\beta_{2} \frac{x^{2}}{L^{2}}+\beta_{3} \frac{x^{3}}{L^{3}}+\beta_{4} \frac{x^{4}}{L^{4}}\right) \tag{9}
\end{equation*}
$$

where $\beta_{0}=\frac{1}{12}\left[12 R+3 c_{b} c_{h}-4\left(c_{b}+c_{h}-c_{b} c_{h} R\right)+6\left(1-c_{b} R-c_{h} R\right)\right], \beta_{1}=-R$,

$$
\beta_{2}=-\frac{1}{2}\left(c_{b} R+c_{h} R-1\right), \beta_{3}=\frac{1}{3}\left(c_{b}+c_{h}-c_{b} c_{h} R\right), \beta_{4}=-\frac{c_{b} c_{h}}{4} .
$$

Substituting Eqs. (4) and (9) into Eq. (7), then rewrite Eq. (7) in dimensionless form

$$
\begin{align*}
& \left(1+\alpha_{1} X+\alpha_{2} X^{2}+\alpha_{3} X^{3}+\alpha_{4} X^{4}\right) \frac{d^{4} \Phi(X)}{d X^{4}}+2\left(\alpha_{1}+2 \alpha_{2} X+3 \alpha_{3} X^{2}+4 \alpha_{4} X^{3}\right) \frac{d^{3} \Phi(X)}{d X^{3}} \\
& +\left(2 \alpha_{2}+6 \alpha_{3} X+12 \alpha_{4} X^{2}\right) \frac{d^{2} \Phi(X)}{d X^{2}}-U^{2}\left(\beta_{0}+\beta_{1} X+\beta_{2} X^{2}+\beta_{3} X^{3}+\beta_{4} X^{4}\right) \frac{d^{2} \Phi(X)}{d X^{2}}  \tag{10}\\
& -U^{2}\left(\beta_{1}+2 \beta_{2} X+3 \beta_{3} X^{2}+4 \beta_{4} X^{3}\right) \frac{d \Phi(X)}{d X}-\lambda^{2}\left(1-c_{b} X-c_{h} X+c_{b} c_{h} X^{2}\right) \Phi(X)=0
\end{align*}
$$

According to the AMDM (Adomian 1994, Hsu et al. 2008, Mao 2012, 2013), $\Phi(X)$ in Eq. (10) can be expressed as an infinite series

$$
\begin{equation*}
\Phi(X)=\sum_{m=0}^{\infty} C_{m} X^{m} \tag{11}
\end{equation*}
$$

where the unknown coefficients $C_{m}$ will be determined recurrently.
Impose a linear operator $G=\frac{d^{4}}{d X^{4}}$, then the inverse operator of $G$ is therefore a 4-fold integral operator defined by

$$
\begin{equation*}
G^{-1}=\int_{0}^{x} \int_{0}^{x} \int_{0}^{x} \int_{0}^{x}(\ldots) d X d X d X d X \tag{12}
\end{equation*}
$$

and

$$
\begin{equation*}
G^{-1} G[\Phi(X)]=\Phi(X)-C_{0}-C_{1} X-C_{2} X^{2}-C_{3} X^{3} \tag{13}
\end{equation*}
$$

Applying both sides of Eq. (10) with $G^{-1}$, we get

$$
\begin{aligned}
G^{-1} G[\Phi(X)]= & G^{-1}\left[-\left(\alpha_{1} X+\alpha_{2} X^{2}+\alpha_{3} X^{3}+\alpha_{4} X^{4}\right) \frac{d^{4} \Phi(X)}{d X^{4}}\right. \\
& -2\left(\alpha_{1}+2 \alpha_{2} X+3 \alpha_{3} X^{2}+4 \alpha_{4} X^{3}\right) \frac{d^{3} \Phi(X)}{d X^{3}} \\
& -\left(2 \alpha_{2}+6 \alpha_{3} X+12 \alpha_{4} X^{2}\right) \frac{d^{2} \Phi(X)}{d X^{2}}
\end{aligned}
$$

$$
\begin{align*}
& +U^{2}\left(\beta_{0}+\beta_{1} X+\beta_{2} X^{2}+\beta_{3} X^{3}+\beta_{4} X^{4}\right) \frac{d^{2} \Phi(X)}{d X^{2}} \\
& +U^{2}\left(\beta_{1}+2 \beta_{2} X+3 \beta_{3} X^{2}+4 \beta_{4} X^{3}\right) \frac{d \Phi(X)}{d X}  \tag{14}\\
& \left.+\lambda^{2}\left(1-c_{b} X-c_{h} X+c_{b} c_{h} X^{2}\right) \Phi(X)\right]
\end{align*}
$$

Substituting Eqs. (11) and (13) into Eq. (14), we get

$$
\begin{equation*}
\Phi(X)=\sum_{m=0}^{3} C_{m} X^{m}+\sum_{m=0}^{\infty} D_{m} X^{m+4}+\sum_{m=0}^{\infty} E_{m} X^{m+5}+\sum_{m=0}^{\infty} F_{m} X^{m+6} \tag{15}
\end{equation*}
$$

And

$$
\begin{align*}
& D_{m}= \frac{\lambda^{2}-(m-1) m(m+1)(m+2) \alpha_{4}+m(m+1) U^{2} \beta_{2}}{(m+1)(m+2)(m+3)(m+4)} C_{m} \\
&+ \frac{-m(m+1)(m+2) \alpha_{3}+(m+1) U^{2} \beta_{1}}{(m+2)(m+3)(m+4)} C_{m+1}  \tag{16}\\
&+\frac{-(m+1)(m+2) \alpha_{2}+U^{2} \beta_{0}}{(m+3)(m+4)} C_{m+2}-\frac{\alpha_{1}(m+2)}{(m+4)} C_{m+3} \\
& E_{m}=\frac{-\left(c_{b}+c_{h}\right) \lambda^{2}+m(m+2)\left(U^{2} \beta_{3}\right.}{(m+1)(m+2)(m+3)(m+4)} C_{m}  \tag{17}\\
& F_{m}=\frac{c_{b} c_{h} \lambda^{2}+m(m+1) U^{2} \beta_{4}}{(m+1)(m+2)(m+3)(m+4)} C_{m} \tag{18}
\end{align*}
$$

Comparing Eq. (11) to Eq. (15), the coefficients $C_{m}(m>4)$ in Eq. (11) can be determined by using the following recurrence relations

$$
C_{m+4}=\left\{\begin{array}{cc}
D_{m} & m=0  \tag{19}\\
D_{m}+E_{m-1} & m=1 \\
D_{m}+E_{m-1}+F_{m-2} & m \geq 2
\end{array}\right.
$$

We may approximate the above solution by the $M$-term truncated series, Eq.(11) can be rewritten as

$$
\begin{equation*}
\Phi(X)=\sum_{m=0}^{M} C_{m} X^{m} \tag{20}
\end{equation*}
$$

Eq. (20) implies that $\sum_{m=M+1}^{\infty} C_{m} X^{m}$ is negligibly small. The number of the series summation limit $M$ is determined by convergence requirement in practice.

From above analysis, it can be found that there are five unknown parameters $\left(C_{0}, C_{1}, C_{2}, C_{3}\right.$ and $\lambda$ ) for the free vibration analysis of the rotating beam. These unknown parameters can be determined by using the boundary condition equations of the beam, and then the natural frequencies and corresponding mode shapes for the rotating beams can be obtained.

## 3. Natural frequencies and mode shapes

The cantilevered boundary conditions of the rotating beam shown in Fig. 1 can be expressed into dimensionless form (Banerjee 2000, Banerjee et al. 2006, Wang and Wereley 2004), wet get

$$
\begin{gather*}
\Phi(0)=\frac{d \Phi(0)}{d X}=0  \tag{21}\\
\frac{d^{2} \Phi(1)}{d X^{2}}=\frac{d^{3} \Phi(1)}{d X^{3}}=0 \tag{22}
\end{gather*}
$$

Substituting Eq. (20) into Eqs. (21) and (22), we get

$$
\begin{equation*}
C_{0}=0, C_{1}=0 \tag{23}
\end{equation*}
$$

According to Eq. (20), the second and third spatial derivative of the mode shapes can be expressed as

$$
\begin{gather*}
\frac{d^{2} \Phi(X)}{d X^{2}}=\sum_{m=0}^{M-2}(m+1)(m+2) C_{m+2} X^{m}  \tag{24}\\
\frac{d^{3} \Phi(X)}{d X^{3}}=\sum_{m=0}^{M-3}(m+1)(m+2)(m+3) C_{m+3} X^{m} \tag{25}
\end{gather*}
$$

By using Eqs. (24) and (25), Eq. (22) can be expressed as

$$
\begin{align*}
& \frac{d^{2} \Phi(1)}{d X^{2}}=\sum_{m=0}^{M-2}(m+1)(m+2) C_{m+2}=2 C_{2}+6 C_{3}+12 C_{4}+20 C_{5}+30 C_{6}+42 C_{7}+\ldots=0  \tag{26}\\
& \frac{d^{3} \Phi(1)}{d X^{3}}=\sum_{m=0}^{M-3}(m+1)(m+2)(m+3) C_{m+3}=6 C_{3}+24 C_{4}+60 C_{5}+120 C_{6}+210 C_{7}+\ldots=0 \tag{27}
\end{align*}
$$

Substituting Eqs. (16)-(19) and (23) into Eqs. (26) and (27), $C_{m}(m>3)$ in Eqs. (26) and (27) can be expressed as linear functions of $C_{2}$ and $C_{3}$ through a recursive way. It means that there are only three unknown parameters ( $C_{2}, C_{3}$ and $\lambda$ ) in Eqs. (26) and (27). So these two boundary condition equations can be expressed as

$$
\begin{align*}
& \frac{d^{2} \Phi(1)}{d X^{2}}=f_{11}(\lambda) C_{2}+f_{12}(\lambda) C_{3}=0  \tag{28}\\
& \frac{d^{3} \Phi(1)}{d X^{3}}=f_{21}(\lambda) C_{2}+f_{22}(\lambda) C_{3}=0 \tag{29}
\end{align*}
$$

${ }^{\text {a}}$ Results from Wang and Wereley (2004)

The explicit forms for $f_{i j}$ in Eqs. (28) and (29) are very complex. However, all the algebraic calculations are finished quickly using symbolic computational software (such as MATLAB).

From Eqs. (28) and (29), the $n$th dimensionless frequency parameter $\lambda(n)$ can be solved by

$$
\begin{equation*}
f_{11}(\lambda) f_{22}(\lambda)-f_{12}(\lambda) f_{21}(\lambda)=\sum_{n=0}^{N} S_{n} \lambda^{n}=0 \tag{30}
\end{equation*}
$$

Notice that Eq. (30) is a polynomial of degree $N$ evaluated at $\lambda$. By using the functions sym2poly and roots in MATLAB Symbolic Math Toolbox, Eq. (30) can be directly solved. The next step is to determine the $n$th mode shape function corresponding to $n$th dimensionless frequency $\lambda(n)$. Substituting the solved $\lambda(n)$ into Eqs. (28) or (29), then $C_{3}$ can be expressed as the function of $C_{2}$.

$$
\begin{equation*}
C_{3}=-\frac{f_{11}(\lambda)}{f_{12}(\lambda)} C_{2}=-\frac{f_{21}(\lambda)}{f_{22}(\lambda)} C_{2} \tag{31}
\end{equation*}
$$

Substituting solved $C_{0}, C_{1}, C_{2}, C_{3}$ and $\lambda(n)$ into equations. Eqs. (16)-(18) and using Eq. (19), all other coefficients $C_{m+4}(m \geq 0)$ can be determined. Then the corresponding $n$th mode shape function can be obtained by using Eq. (20).

## 4 Numerical calculations

In order to verify the proposed method to analyze the free vibration of the rotating tapered beam shown in Fig. 1, several numerical examples will be discussed in this section.

As mentioned earlier, the closed-form series solutions of mode shape functions in Eq. (20) will have to be truncated in numerical calculations. It is important to check how rapidly the dimensionless natural frequencies $\lambda(n)$ computed through AMDM converge toward the exact

Table 2 The first five dimensionless natural frequencies $\lambda(n)$ for a beam with different dimensionless rotating speed $U$ and offset length $R$ when taper ratios $c_{b}=0$ and $c_{h}=0.5$

${ }^{a}$ Results from Banerjee et al. (2006)
${ }^{\mathrm{b}}$ Results from Banerjeea and Jackson (2013)
value as the series summation limit $M$ is increased. To examine the convergence of the solution, a beam with dimensionless rotating speed $U=12$ and dimensionless offset length $R=0$ is considered. The taper ratios of the beam are assumed as $c_{b}=0$ and $c_{h}=0.5$. Table 1 shows the dimensionless natural frequencies $\lambda(n)$ as the function of the series summation limit $M$. Clearly, the $\lambda(n)$ converges very quickly as the series summation limit $M$ is increased. If $M=50$ is used, the first fourth $\Omega_{1}$ can be kept accurate to the sixth decimal place. The excellent numerical stability of the solution can also be found in Table 1.

For brief, the series summation limit $M$ in Eq. (20) will be simply truncated to $M=60$ in all the subsequent calculations. The dimensionless natural frequencies $\lambda(n)$ are kept accurate to the sixth decimal place for comparison purpose. To further check the accuracy of the proposed method, the first five dimensionless natural frequencies $\lambda(n)$ for beams with taper ratios ( $c_{b}=0, c_{h}=0.5$ ) and ( $c_{b}=c_{h}=0.5$ ) under different rotating speeds $U$ and offset lengths $R$ are listed in Tables 2 and 3, respectively. Those calculated results are compared with those listed in the publications (Banerjee et al. 2006, Wang and Wereley 2004, Ozdemir and Kaya 2006b) and excellent agreement is found. Due to the stiffening effect of the centrifugal axial force acting on the beam, it can also be found
that the natural frequencies increase when the rotating speed or offset length increases, as expected.

Fig. 2 shows the first five mode shapes with different taper ratios and rotating speeds when the offset length $R=0$. From Fig. 2, it can be found that the discrepancies between the mode shapes under different rotating speeds become smaller as increasing the modal number. However, the natural frequencies are quite different, as shown in Tables 2 and 3.

Fig. 2 The first five mode shapes for the rotating tapered beams when offset length $R=0$. Columns 1,2 and 3 are $\left(c_{b}=c_{h}=0\right),\left(c_{b}=0, c_{h}=0.5\right)$ and $\left(c_{b}=c_{b}=0.5\right)$ respectively. Rows $1,2,3,4$ and 5 are the first, second, third, fourth and fifth mode respectively

Table 4 The effect of taper ratios ( $c_{b}$ and $c_{h}$ ) on the dimensionless natural frequencies $\lambda(n)$ for a tapered beam when the dimensionless offset length $R=1$ and the dimensionless rotating speed $U=5$

Fig. 3 The first four mode shapes for the rotating beams under different taper ratios when $U=5$ and $R=1$. Columns 1,2 and 3 are $c_{b}=0.1,0.3$ and 0.5 respectively. Rows $1,2,3,4$ and 5 are the first, second, third fourth and fifth mode respectively

Next, the beams with different width and thickness taper ratios are discussed. Because the proposed method based on AMDM technique offers a unified and systematic procedure for vibration analysis for the rotating tapered beams. The modification of taper ratios from one case to another is as simple as changing the values of the taper ratios $c_{b}$ and/or $c_{h}$. And it does not involve any changes to the solution procedures or algorithms.

Table 4 illustrates the effect of the taper ratios on the first four natural frequencies when the dimensionless rotating speed $U=5$ and offset length $R=1$. From Table 4, it can be found that the first natural frequency increases when the width taper ratio $c_{b}$ and/or thickness taper ratio $c_{h}$ increases. However, on the contrary, for the second, third and fourth modes, the thickness taper ratio $c_{h}$ has an almost linear decreasing effect on the natural frequencies, and the width taper ratio $c_{b}$ has little influence on the natural frequencies. This conclusion is well agreed with the results in publications (Banerjee et al. 2006, Ozdemir and Kaya 2006b). Fig. 3 shows the effect of the taper ratios on the first five mode shapes under different rotating speeds and offset lengths. It can be found that the discrepancies between the mode shapes under different taper ratios become much large with increasing the mode number.

## 5. Conclusions

In this paper, free vibrations of the rotating tapered cantilever Euler-Bernoulli beams are carried out using Adomian modified decomposition method (AMDM). The advantages of the AMDM are its fast convergence of the solution and its high degree of accuracy. Natural frequencies and corresponding mode shapes with various taper ratio, offset length and rotating speed are presented. Furthermore, the natural frequencies obtained by using AMDM are in excellent agreement with published results. The effects of the offset length, taper ratios and rotating speed on the natural frequencies and corresponding mode shapes are investigated. The numerical results show that the natural frequencies increase with the increase in the offset length and/or rotating speed. The changes of the mode shapes under different rotating speeds become smaller as increasing the modal number. For given rotating speed, the first natural frequency of the tapered beam increases when the width and/or thickness taper ratio increases.
